## Unleashing the most effective oral health education intervention technique for improving the oral hygiene status and oral health knowledge in visually impaired young individuals: A systematic review and meta-analysis

Apurva P Deshpande, Anil V Ankola, Roopali Sankeshwari, Sagar Jalihal, Deepika V Bhat, Abhra Roy Choudhury, Ram Surath Kumar, Atrey Pai Khot

#### Abstract:

Appropriate oral health education (OHE) plays a vital role in prevention of oral diseases and would bridge the gap between dentists and visually impaired individuals. Hence, this systematic review was planned with an aim to evaluate effectiveness of various OHE techniques on the oral hygiene status and oral health knowledge of visually impaired young individuals. An electronic search extended to September 30, 2020 was conducted on PubMed, Wiley, ProQuest, ScienceDirect, Cochrane library, EBSCO, and Google Scholar. Two independent reviewers assessed the studies using a two-stage process; data were extracted according to PRISMA statement. Risk of bias assessment of selected studies was executed according to the study designs. Meta-analysis using the random-effects model was conducted for the outcomes for all oral health education techniques using STATASE 16.1 software. Hand and electronic search identified 3829 articles. After screening for titles and duplicates, 37 articles were retrieved, which were screened through abstract and full text. Of the 37 articles, 17 articles were included for qualitative synthesis, and out of that, 13 were for meta-analysis. Ten variations in oral health education (OHE) techniques were used in the included 17 studies to impart oral health education to visually impaired young individuals. Overall, all OHE techniques demonstrated a positive impact on oral hygiene status. The pooled overall cumulative mean difference of the oral hygiene status after imparting education in ATP, Audio, and Braille was 1.33 [1.06, 1.59], 1.76 [1.11, 2.42], and 1.96 [1.40, 2.55], respectively. An appropriate OHE technique boosts confidence in visually impaired young individuals, making the learning process an enjoyable experience. Use of either Braille or the ATP OHE technique was found to be a reliable and useful method to improve oral hygiene of visually impaired young individuals.

#### Keywords:

Audio, audio tactile performance, Braille, oral health education, oral hygiene status, visually impaired

organization (WHO) estimates that there are 36 million individuals who suffer from from visual impairment or blindness.<sup>[3]</sup>

### Material and Methods

One of the major public health concerns is childhood blindness. There are around 1.42 million and 17.52 million children suffering from blindness and moderate to severe visual impairment, respectively.<sup>[4]</sup> The most common impact of loss of vision is the inability of the people to maintain oral health as they are not in a position to identify oral disease and may be unable to take immediate action unless informed of the situation.<sup>[5]</sup>

Oral health care needs of visually impaired children remain largely neglected. It was found that only 29.4% of visually impaired children had good oral hygiene in a study conducted by Al – Qahtani *et al.*<sup>[6]</sup> High caries prevalence and poor oral hygiene were also reported in other studies that were conducted worldwide. Maintenance of proper oral hygiene is a matter of concern in visually impaired children.<sup>[7,8]</sup>

Visually impaired children find it challenging to learn basic life skills as they cannot perceive the world like normal children. They rely on their care-givers or parents for performing routine activities including oral hygiene practices, negligence of which can lead to poor oral hygiene. Appropriate oral health education plays a vital role in prevention of oral diseases and would bridge the gap between dentists and visually impaired individuals.<sup>[9,10]</sup>

The literature quotes various oral health intervention techniques [Braille text, verbal method, audio tactile performance (ATP) technique, and their combinations] which are practiced to deliver oral health education in visually impaired children. Of the many OHE techniques, the most trending oral health education technique is the ATP technique, which was developed by Hebbal and Ankola.<sup>[11-14]</sup>

In spite of availability of various oral health education techniques, there is always a dilemma to select an appropriate technique to impart knowledge to visually impaired children. Hence, this systematic review was planned with an aim to assess the most effective OHE technique in visually impaired young individuals for prevention of oral diseases and maintenance of good oral hygiene with the following objective: to assess the effect of various OHE techniques on oral health knowledge of visually impaired young individuals. To the best of our knowledge, this systematic review is the first of its kind where effectiveness of ten kinds of OHE techniques on oral hygiene status and oral health knowledge is evaluated among visually impaired children.

## Protocol development and registration

This systematic review and meta-analysis was conducted according to the preferred reporting items for the systematic review and meta-analysis (PRISMA) statement and registered in PROSPERO under number CRD42020200286. The following focused question in the patient, intervention, and outcome (PIO) format was proposed: "How do different OHE techniques (ATP, ATP combined with Braille or verbal, Braille, verbal, tactile, and a combination of verbal, tactile, and braille) influence the oral hygiene status and oral health knowledge of 5–20 years old visually impaired young individuals?"

#### Search strategy

The electronic search was performed with the databases PubMed, ProQuest, Wiley, ScienceDirect, EBSCO, Cochrane Library, and Google Scholar with a platform-specific search strategy consisting of combinations of controlled terms (MeSH) and text words. Additional hand searching of the literature was also performed with Special Care in Dentistry Journal, Journal of Education and Health Promotion, and International Journal of Pediatric Dentistry. No language restrictions were put, although studies included were in English language. The keywords for search were selected by reviewing the literature. MeSH terms, keywords, and other free terms related to PIO questions were used with Boolean operators (OR, AND) to combine searches. The search strategy terms included "Visually impaired", "Oral health education", "Oral hygiene status", "Audio-tactile performance technique", "Braille", "Audio", "Tactile", "Children", and "Young" with no additional filters.

#### Eligibility criteria

### Inclusion criteria (PIOS format)

**P** (**Population**): Visually impaired children/young individuals in the age group of 5–20 years.

**I** (Intervention): The ATP technique alone or the ATP technique combined with the Braille technique, the verbal technique, the tactile technique, and the combination of Braille, tactile, and verbal techniques.

#### O (Outcome):

- Primary outcome: Oral hygiene status
- Secondary outcome: Oral health knowledge.

**S** (Studies): Clinical trials, randomized controlled trials (RCTs), cluster randomized trials, quasi-experimental studies, and non-randomized studies.

#### Exclusion criteria

Observational study designs, case reports, case series, cross-sectional studies, and reviews were not

considered. Articles reporting only abstracts were also excluded.

#### Screening process

The search and screening process were carried out by two independent reviewing authors, AD and AA. Title and abstract screening was done at the first stage. The second stage involved complete careful reading of the selected articles and was analyzed per eligibility criteria (inclusion/exclusion) for future data extraction. Discrepancies among authors/reviewers were resolved by the third author, RS through careful discussion. The level of agreement was calculated through Cohen's kappa between the two reviewers and was 0.92 for titles and abstracts and 0.94 for full texts. Finally, the search yielded 17 studies which were included in the systematic review.

#### **Data extraction**

A standardized data extraction form was prepared by AD in Microsoft Excel and assessed by another author, AA. The data were extracted independently from the full-text articles selected for inclusion using a standardized pre-designed format. The following items were assessed during data extraction of the individual studies: article details such as author names, country and the year of study, study setting and design, aim of the study, age groups, sample size, type of OHE technique used, indices used to assess oral hygiene status, knowledge assessment, and author conclusion. Any discrepancies within the studies were discussed and resolved between the two authors.

### Assessments of the risk of bias and quality

Quality assessment of the selected studies was executed by using the Cochrane Collaboration Tool (http:// ohg.-cochrane.org) for RCTs including random sequence generation, allocation concealment, blinding of participants, incomplete outcome data, and selective reporting, and other bias and quality assessments of non-randomized studies were performed using ROBINS - I tool. "Traffic light" plots of the domain-level judgments for each individual result and weighted bar plots of the distribution of risk-of-bias judgments within each bias domain were created using "robvis tool".<sup>[15-17]</sup>

#### **Statistical analysis**

STATASE 16.1 software was used for statistical analysis. Differences in means and effect size were used as principal summary measures. Forest plots and funnel plots were generated to visualize the difference between various intervention groups and publication bias. The overall estimated effect was categorized as significant, where P < 0.05. Statistical heterogeneity was tested using I2 statistics (0–40%, not important; 30–60%, moderate heterogeneity; 50–90%, representing substantial

heterogeneity; 75–100%, considerable heterogeneity) as described by the PRISMA protocol for writing systematic review.

### Results

#### Literature search

In the systematic review for evaluation of various oral health education techniques in management of the oral hygiene status in visually impaired children, the process of selection was initiated by stepwise screening of the articles. A total of 419 records were identified through data search using the search strategy in PubMed and Cochrane. A total of 963 records were identified through data search using the search strategy in Proquest, Wiley, and Science direct. A total of 933 and 1512 records were identified through Ebsco and Google Scholar, respectively. Two articles were identified through the Gray literature. The total article number arrived to be 3829. The second step was screening through titles, and after screening through titles, 3,277 articles were excluded because they were not related to the objectives of the systematic review. A total of 552 articles which remained were screened for duplicates through Endnote Software VersionX7. Out of 552 articles, 515 articles were found to be duplicates.

The remaining 37 articles were screened through abstracts and full text screening as the next step. Out of 37 articles, 20 were excluded for various reasons, with one being systematic review, two being conference proceedings, 11 not meeting the inclusion criteria (age range of the participants, inclusion of SHCN children other than visual impairment), and six denoting themselves as descriptive studies [Figure 1]. Finally, 17 articles were qualitatively analyzed, after which they were included in the systematic review [Table 1]. Ten different oral health education techniques were used in the included 17 studies to impart oral health education to visually impaired children.

#### **Study characteristics**

There are 17 studies<sup>[10-14,18-29]</sup> included in this systematic review. The general characteristics of each study are presented in Table 1. The majority of the included studies are of Indian origin,<sup>[10,11-14,18-24,25,28,29]</sup> with one study each being conducted in Iran<sup>[27]</sup> and Indonesia.<sup>[26]</sup> There are six randomized controlled trials<sup>[10,11,14,24,27,28]</sup> and 11 non-randomized controlled trials<sup>[12,13,18-23,25,26,29]</sup> included in this systematic review.

The age of the participants ranged from 5 to 20 years old with complete visual impairment. They did not have any other systemic condition and were not using any chemical mode of plaque control or were on any medication during the entire study period.

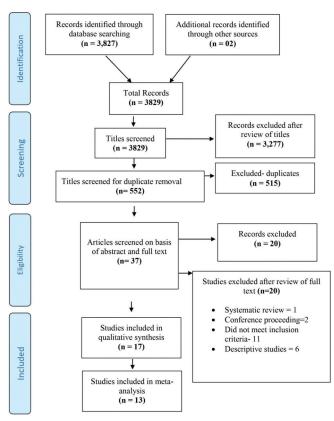

Figure 1: Flowchart diagram depicting the process of selection and exclusion of articles at each step

All the studies had procured informed consent from the parents and guardians prior to the conduct of the study. A total of 1,663 visually impaired children were part of study analysis with 330 in the Braille group,<sup>[11,18,20,24,28,29]</sup> 183 in the Audio group,<sup>[12,23,24,26,28]</sup> 247 in the Braille + Audio group,<sup>[14,21,22,10,29]</sup> 393 in the ATP group,<sup>[10-13,20,25,27]</sup> 60 in the ATP + Braille group,<sup>[11,20]</sup> 140 in the Audio + Tactile + Braille group,<sup>[14,19,22,24]</sup> 60 in the Audio + Tactile group,<sup>[14,22]</sup> 74 in the Braille + Tactile group,<sup>[23]</sup> 66 in the ATP + Audio group,<sup>[27]</sup> and 40 in the Tactile group.<sup>[24]</sup>

Significant methodological variability was found in the included studies; thus, studies were categorized as follows:

- (a) Effect of ten different forms of OHE techniques on the oral hygiene status of visually impaired children.
- (b) Effect of different forms of OHE techniques assessed by different oral hygiene indices.
- (c) Effect of various OHE techniques on oral health knowledge of visually impaired children.

OHE was given by dental professionals in all the included studies. Overall, there was no attrition observed at the end of the follow-up period. Different follow-up periods were observed in all the included studies. Three of the studies had a follow-up duration of up to 4 weeks,<sup>[11,26,29]</sup> five studies had a 3-month follow-up period,<sup>[10,12,25,27,28]</sup>

and nine studies<sup>[13,14,18-24]</sup> had a follow-up period of more than 3 months.

#### Risk of bias in included studies

Eleven NRCTs and six RCTs were assessed for risk of bias. All six RCTs included in the systematic review had a low risk of bias. Four studies had unclear or no information bias with respect to the blinding of the participants. Three studies had no information with regard to blinding of the outcome assessment. One study reported incomplete outcome data [Figure 2a and 2b].

Out of 11 NRCTs, five studies demonstrated a low risk of bias, five studies showed a moderate risk of bias, and one study had a high or serious risk of bias. Four studies had a moderate risk of bias, and two studies had a serious risk of bias with regard to bias because of confounding. Two studies had moderate and serious risks of bias, respectively, in bias because of selection of the participants category. Two studies demonstrated a moderate risk of bias in classification of interventions. All three studies had a moderate risk of bias with respect to bias because of deviation from the intended interventions. All 11 studies demonstrated no information or were unclear with respect to bias because of missing data. One study showed a high risk, and two studies showed a moderate risk of bias in bias in the measurement of outcomes. Four studies demonstrated a moderate risk of bias in selection of the reported result category [Figure 2a and 2b].

Considering the overall risk of bias for both the study designs, all the randomized controlled trial studies reported a low risk of bias. More than 25% of non-randomized controlled trials reported low and moderate risks of bias, respectively, whereas less than 25% of non-randomized controlled trials reported a high risk of bias [Figure 3a and 3b].

## Effects of oral health education intervention techniques

Meta-analysis was performed to assess the impact of all oral health education techniques on the oral hygiene status and oral health knowledge of visually impaired children. The main interest was to assess the best OHE intervention technique among the ten oral health education techniques which were used in the studies. Thirteen studies were included for meta-analysis to assess the oral hygiene status post various oral health education interventions.<sup>[10,12-14,20-25,27-29]</sup>

Out of these 13 studies, four studies pooled the mean effect of six different oral health education interventions on oral health knowledge of visually impaired children.<sup>[10,24,25,29]</sup> The gingival index, plaque

index, and oral hygiene index – simplified scores before and after oral health education interventions – were used to construct the forest plots. The results obtained from the analysis showed high precision values while considering 95% confidence interval.

### **Effect of ten different forms of OHE techniques on oral hygiene status of visually impaired children** *ATP* + *Audio*

Sharififard *et al.*,  $2020^{[27]}$  assessed the effect of the combination of ATP + Audio OHE technique on the

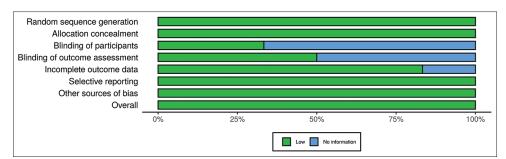

Figure 3a: Overall Risk of Bias among Randomized controlled trials

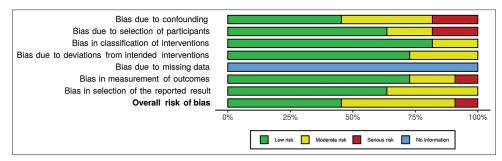

Figure 3b: Overall Risk of Bias among Non - Randomized controlled trials

oral hygiene of visually impaired children. The pooled overall mean of the oral hygiene status after imparting education in the ATP + Audio OHE technique was found to be 1.34 [Figure 4c].

#### *ATP* + *Braille*

Tiwari BS *et al.*, 2019<sup>[20]</sup> compared effectiveness of the ATP + Braille OHE technique on the oral hygiene status of visually impaired children. Pre- and post-values of both plaque and gingival indices were used to assess the oral hygiene status. The pooled overall mean of the oral hygiene status after imparting education in the ATP + Braille OHE technique was found to be 1.26 [Figure 4d].

#### *Braille* + *Tactile*

Sardana D.*et al.*, 2019<sup>[23]</sup> assessed the combination of Braille + Tactile OHE technique for improving the oral hygiene status in visually impaired children. The pooled overall mean of the oral hygiene status after imparting education in the Braille + Tactile OHE technique was found to be 1.13 [Figure 4e].

#### Tactile

Ganapathi A K *et al.*, 2015<sup>[24]</sup> assessed the effect of the tactile OHE technique on the oral hygiene of visually impaired children. The pooled overall mean of the oral hygiene status after imparting education in the tactile OHE technique was found to be 2.07 [Figure 4f].

#### *ATP technique*

Six studies (Tiwari BS *et al.*, 2019; Hebbal M *et al.*, 2012; Krishnakumar R *et al.*, 2016; Diptajit Das. *et al.*, 2019; Sharififard *et al.*, 2020; and Deolia S. *et al.*, 2019)<sup>[10,12,13,20,25,27]</sup>

assessed the effectiveness of the ATP OHE technique on the oral hygiene status of visually impaired children. The pooled overall mean of the oral hygiene status after imparting education in the ATP OHE technique was found to be 1.33 [Figure 4a].

#### *Braille technique*

Four studies (Tiwari BS *et al.*, 2019; Mahantesha T *et al.*, 2015; Bhor K *et al.*, 2016 and Ganapathi A K *et al.*, 2015)<sup>[20,24,28,29]</sup> assessed the effect of the Braille OHE technique on the oral hygiene status of visually impaired children. The pooled overall mean of the oral hygiene status after imparting education in Braille was found to be 1.97 [Figure 4b].

#### *Braille* + *Audio technique*

The effect of the Braille + Audio technique on the oral hygiene status of visually impaired children was evaluated by Aggarwal T. *et al.*, 2019; Chowdary PB. *et al.*, 2016; Bhor K *et al.*, 2016; Diptajit Das *et al.*, 2019; and Gautam A. *et al.*, 2018.<sup>[10,14,21,22,29]</sup> The pooled overall mean of the oral hygiene status after imparting education in the Braille + Audio OHE technique was found to be 0.71 [Figure 4g].

#### *Audio technique*

Krishnakumar R *et al.*, 2016; Sardana D.*et al.*, 2019; Mahantesha T *et al.*, 2015; and Ganapathi A K *et al.*, 2015<sup>[12,23,24,28]</sup> evaluated the effect of the Audio OHE technique on the oral hygiene status of visually impaired children. The pooled overall mean of the oral hygiene status after imparting education in Audio was found to be 1.76 [Figure 4h].

Figure 4a: Effect of the ATP OHE technique on the oral hygiene status of visually impaired children

#### *Audio* + *Tactile* + *Braille*

Ganapathi A K *et al.*, 2015; Chowdary PB. *et al.*, 2016; and Gautam A. *et al.*, 2018<sup>[14,22,24]</sup> evaluated the combination of Audio + Tactile + Braille for improving the oral hygiene status in visually impaired children. The pooled overall mean of the oral hygiene status after imparting education in the Audio + Tactile + Braille OHE technique was found to be 0.76 [Figure 4i].

#### Audio + Tactile

Chowdary PB *et al.*, 2016 and Gautam A. *et al.*, 2018<sup>[14,22]</sup> assessed the combination of Audio + Tactile OHE technique for improving the oral hygiene status in visually impaired children. The pooled overall mean of the oral hygiene status after imparting education in the Audio + Tactile OHE technique was found to be 0.42 [Figure 4j].

## Effect of different forms of OHE techniques assessed by different oral hygiene indices

## Effect of OHE techniques on gingival scores assessed by Loe and Silness Gingival indices

The impact of various OHE techniques on gingival scores in four different studies<sup>[10,20,22,23]</sup> assessed by Loe and Silness gingival indices is portrayed in Figure 5b. The highest mean gingival score reduction was obtained in the combination of Braille + Audio OHE technique being [2.15 (1.35, 2.95)]. The pooled overall mean of the

oral hygiene status using Loe and Silness gingival indices after imparting education in different OHE techniques was found to be 0.72 [Figure 5b].

## *Effect of OHE techniques on plaque scores assessed by Silness and Loe Plaque indices*

There was substantial evidence of mean plaque reduction observed in six studies<sup>[12,13,20-23]</sup> that included different OHE techniques to assess plaque scores before and after imparting oral health education. The highest mean plaque reduction was observed in the ATP + Braille technique [0.95 (0.83, 1.07)], followed by ATP [0.78 (0.64, 0.92)]. The pooled overall mean of the oral hygiene status using Silness and Loe Plaque indices after imparting education in different OHE techniques was found to be 0.49 [Figure 5a].

## Effect of OHE techniques on oral hygiene status assessed by OHI-S index

There was substantial evidence of improvement of oral hygiene status using OHI-S index, which is portrayed in Figure 5c.<sup>[27,29]</sup> The highest improvement in oral hygiene status was noticed in the ATP OHE technique [1.31 (1.07, 1.55)]. The pooled overall mean of the oral hygiene status using OHI-S index after imparting education in different OHE techniques was found to be 0.80 [Figure 5c].

# Effect of OHE techniques on oral hygiene status assessed by PHP index

The effect of five different OHE techniques on oral hygiene status was assessed in two studies<sup>[14,28]</sup> using PHP index. The highest improvement in oral hygiene status was observed in the Braille OHE technique [1.41 (1.20, 1.62)]. The pooled overall mean of the oral hygiene status using PHP index after imparting education in different OHE techniques was found to be 0.75 [Figure 5d].

## Effect of OHE techniques on plaque scores assessed by Quigley Hein plaque index

There was substantial evidence of improvement of plaque status in visually impaired children after

imparting oral health education through various OHE techniques.<sup>[24,25]</sup> The highest mean plaque reduction was observed in the ATP technique [1.15 (0.56, 1.08)]. The pooled overall mean of the oral hygiene status using Quigley Hein Plaque index after imparting education in different OHE techniques was found to be 0.82 [Figure 5e].

visually impaired children. The overall pooled mean before imparting oral health education was estimated to be 2.29. The overall pooled mean increased to 8.63 after imparting oral health education in visually impaired children<sup>[10,24,25,29]</sup> [Figure 6a and 6b].

### Discussion

One of the most widely accepted approaches in prevention of oral diseases and enhancing the oral hygiene status is appropriate oral health education. Oral

Figure 4j: Effect of Audio + Tactile OHE technique on oral hygiene status of visually impaired children

health education has an upper hand when compared to any other preventive strategy as it not only helps in reduction of the incidence of oral ailments but also is easy to implement and cost-effective. An appropriate OHE technique will help the beneficiary to inculcate and reinforce new behavior. It will help to maintain a healthy lifestyle that will promote and improve an individual's general and oral health.<sup>[11,30]</sup> A distinctive approach with time and patience is essential for teaching good oral hygiene practices to visually impaired children.

For oral hygiene status outcome, 13 studies were included in meta-analysis. Six studies assessed Loe and Silness plaque index,<sup>[12,13,20-23]</sup> four studies assessed Loe and Silness gingival indices,<sup>[10,20,22,23]</sup> two studies assessed PHP index,<sup>[14,28]</sup> two studies assessed Quigley Hein Plaque index,<sup>[24,25]</sup> and two studies assessed oral hygiene index – simplified (OHI-S).<sup>[27,29]</sup> The majority of the studies suggest a positive effect of different OHE techniques on plaque level reduction, improvement of gingival scores, and improvement of the oral hygiene status calculated through PHP index and OHI-S. For plaque reduction, which was assessed by Loe and Silness plaque indices and Quigley Hein plaque index, the "ATP" OHE technique was found to be superior to other OHE techniques. The combination of "Braille + Audio" was the most effective as compared to other OHE techniques in improving gingival scores which were

assessed using Loe and Silness gingival indices. "Braille" and "ATP" were superior in improving the oral hygiene status, which were assessed with the help of PHP index and OHI-S Index, respectively.

We conducted meta-analysis separately for assessing the independent effect of ten different OHE intervention techniques to see the overall improvement of the oral hygiene status. Among the different OHE techniques, it can be suggested that conventional "Braille" is the best OHE technique for improving the oral hygiene status in visually impaired children, followed by "Audio" and "ATP". The least improvement in the oral hygiene status post the OHE technique was seen with "Audio + Tactile".<sup>[10,12-14,20-25,27-29]</sup>

Meta-analysis was also conducted to assess the oral health knowledge of visually impaired children. Four studies which were composed of six different OHE techniques were assessed. All four studies showed a positive effect of six different OHE techniques on the oral health

Figure 6a: Oral health knowledge of visually impaired children before OHE

knowledge of visually impaired children.<sup>[10,24,25,29]</sup> The pooled pre-OHE mean of the "Audio + Tactile + Braille"

OHE technique was found to be the most effective in improving oral health knowledge, followed by the "ATP" OHE technique. This may be attributed to the fact that visually impaired children would grasp more knowledge when it is imparted with a multi-sensory approach which includes verbal interaction, tactile experience, and the help of Braille.

A meta-analysis performed by Niloufar Abedi in 2018 to investigate the effective educational interventions on improving oral and dental health improvement in Iran by following the metaanalysis model concluded that educational interventions are beneficial in improving dental health in Iran. Our results also highlight improvement in the oral hygiene status and oral health knowledge post educational interventions.<sup>[31]</sup>

Systematic review conducted by Bhor K *et al.* (2020)<sup>[32]</sup> concluded that newer OHE methods (Braille, ATP) showed short-term improvement in oral hygiene behavior. However, evidence of this review is limited because OHE methods were evaluated over a short period of time. Also, findings of this systematic review did not explicitly mention the best OHE technique. It also highlighted the fact that all the studies were conducted while the students were not sensitized to the newer methods, which might have an added influence on their level of grasping of knowledge that was imparted.

The prime objective of our systematic review was to assess the best OHE technique to impart oral health

Figure 6b: Oral health knowledge of visually impaired children after OHE

education in visually impaired children. Hence, ten different combinations of OHE techniques were assessed in this systematic review. We found that all the oral health education interventions were imparted by oral health professionals. Visually impaired children are dependent on their parents or guardians for their daily activities. Hence, use of an appropriate OHE technique to enlighten visually impaired children would make them more independent and confident in maintaining their oral hygiene. These techniques can also be taught to parents and guardians to reinforce oral health education knowledge in these children periodically.

#### Limitation of the systematic review

Large heterogeneity was observed among the studies. Also, future studies should focus more on a larger sample size and longer follow-up periods. Sensitization to OHE techniques prior to the conduct of the study should be taken into consideration in any upcoming future studies.

### Conclusion

Regular motivation and reinforcement from dental professionals, teachers, parents, and guardians play a significant role in promoting the oral health of visually impaired children. Use of an appropriate OHE technique would boost their confidence and would make the learning process an enjoyable experience. Braille was the most effective OHE technique to improve oral hygiene of visually impaired children, followed by the Audio OHE technique and ATP OHE technique. "ATP" and "ATP + Braille" OHE techniques were the most effective in plaque reduction and oral hygiene status improvement. Based on our overall observation, it can be concluded that use of either the conventional Braille or ATP OHE technique alone without any combinations to impart OHE is the most reliable and useful method to improve the oral hygiene of visually impaired children and young individuals.
